

# **Dependency of tsunami simulations on advection scheme, grid resolution, bottom friction and topography**

C. Wekerle, S. Harig, W. Pranowo, A. Androsov, A. Fuchs,  
N. Rakowsky, J. Schröter, S. Danilov and J. Behrens

# Outline

- The tsunami model *TSUNAWI* 
  - Numerical concepts and inundation scheme
- The Okushiri tsunami 1993
  - Influence of advection scheme, grid resolution, bottom friction on simulation results
- A worst case scenario for Padang
  - Influence of topography data on inundation
- Conclusion

# Shallow water equations

Continuity equation:

$$\partial_t \eta + \nabla \cdot (\mathbf{v}H) = 0$$

Momentum equation:

$$\partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} + \mathbf{f} \times \mathbf{v} + g \nabla \eta + \frac{gn^2 \mathbf{v} |\mathbf{v}|}{H^{4/3}} - \nabla \cdot (A_h \nabla \mathbf{v}) = 0$$

advection
Coriolis
pressure gradient
bottom friction
viscosity

where

$\mathbf{v} = (u(t, x, y), v(t, x, y))$ : horizontal velocity

$H = h(x, y) + \eta(t, x, y)$ : total water depth

Boundary Conditions:

$$\mathbf{v} \cdot \mathbf{n} = \sqrt{\frac{g}{H}} \eta, \quad (x, y) \in \partial\Omega_1$$

$$\mathbf{v} \cdot \mathbf{n} = 0, \quad (x, y) \in \partial\Omega_2$$

Initial Conditions:

$$\mathbf{v}|_{t=0} = 0$$

$$\eta|_{t=0} = \eta_0$$

# Discretization

## Finite element spatial discretization:

non-conforming mixed  $P_1$ - $P_1^{nc}$  (Hanert et al., 2005)

Linear conforming shape functions for  $\eta$

Linear non-conforming shape functions for  $v$

## Explicit time stepping scheme:

Leap frog with Robert-Asselin filter

## Inundation: Extrapolation scheme

„Dry node concept“ by Lynett et al., 2002

# The Okushiri Tsunami 1993 ( $M_w$ 7.8)

max. uplift: 4.87m  
max. depression: -1.12m

Initial  
uplift  
distribution

Takahashi et al, 1995

Field benchmark for the validation of tsunami models (Synolakis, NOAA, 2007)

- Initial condition, tide gauge data and bathymetry provided by NOAA
- Very high runup up to 30m at Monai (west coast of Okushiri island)

# Mesh Generation

Mesh refinement is based on the CFL criterion and bathymetry:

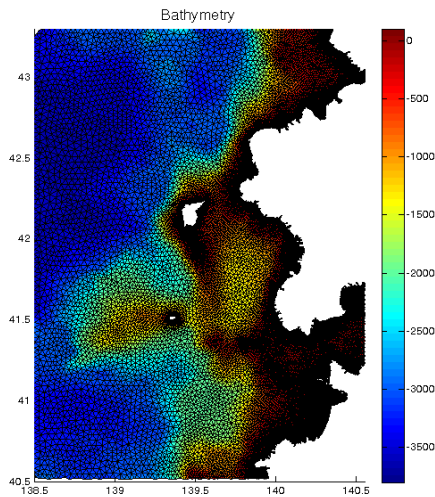

$$\Delta x \leq \min \left( k_1 \sqrt{gh}, k_2 \frac{h}{\nabla h} \right)$$

→ fine resolution at the shoreline and at regions of steep bathymetry, coarse mesh in the deep ocean

For the Okushiri testcase, four meshes with different resolution are used:

**Mesh 1 (fine\_mesh):**

# nodes: 309 410  
min. res. 50m  
max. res. 3km

**Mesh 2 (medium\_mesh):**

# nodes: 103 361  
min. res. 100m  
max. res. 6km

**Mesh 3 (coarse\_mesh):**

# nodes: 45 028  
min. res. 150m  
max. res. 9km

**Mesh 4:**

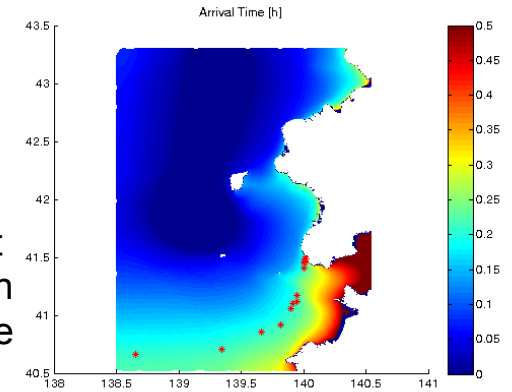

# nodes: 214 124  
local refinement in the Monai area:  
min. res. 10m  
max.res. 6km

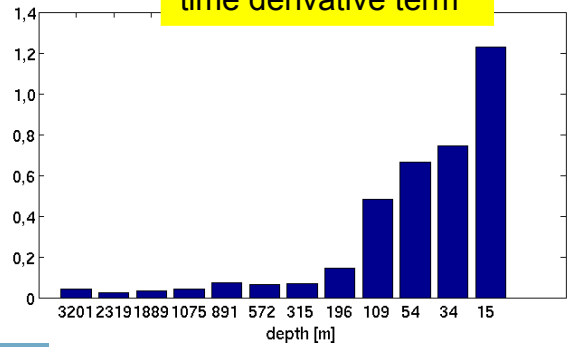

# Fractions of terms in the momentum equation dependent on depth

Locations of different depth on 12 min isochrone

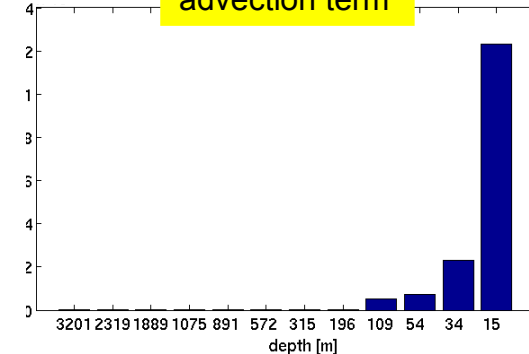

Arrival time

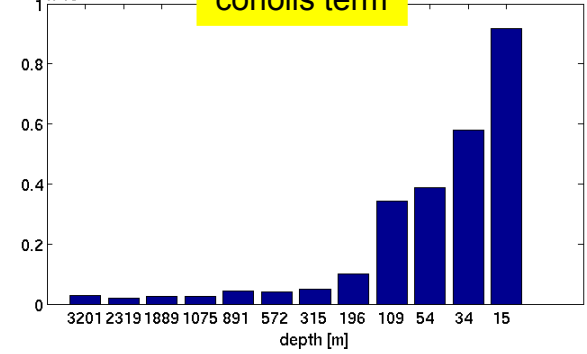

$\times 10^{-2}$  time derivative term

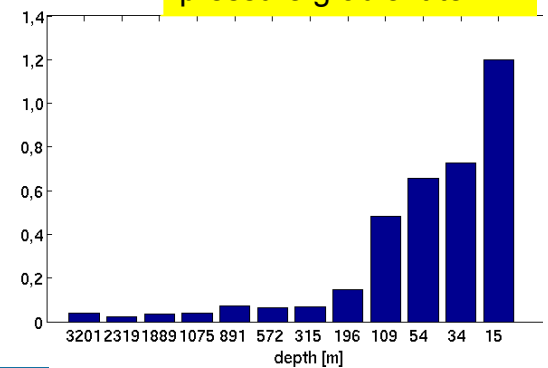

$\times 10^{-3}$  advection term

$\times 10^{-4}$  coriolis term

$\times 10^{-2}$  pressure gradient term

$\times 10^{-5}$  friction term

$\times 10^{-5}$  viscosity term

# Momentum eq. with and without advection

Division of nodes into 3 categories:

- depth < 200m
- 200m < depth < 10m
- 10m < depth < 0m

Histograms of mwh:  $\eta_{\max}^{\text{linear}} - \eta_{\max}^{\text{non-linear}}$

Histograms of max. velocity:  $|V_{\max}|^{\text{linear}} - |V_{\max}|^{\text{non-linear}}$

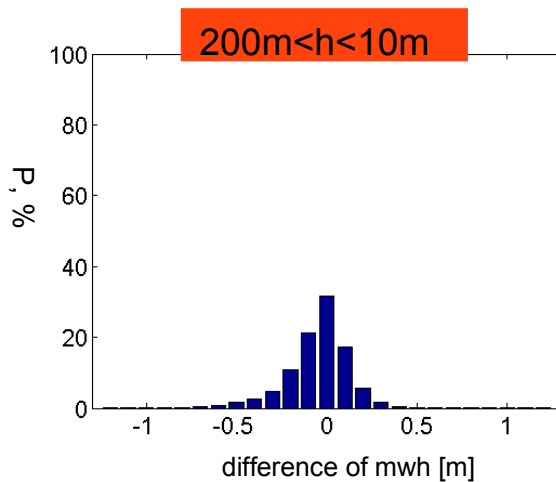

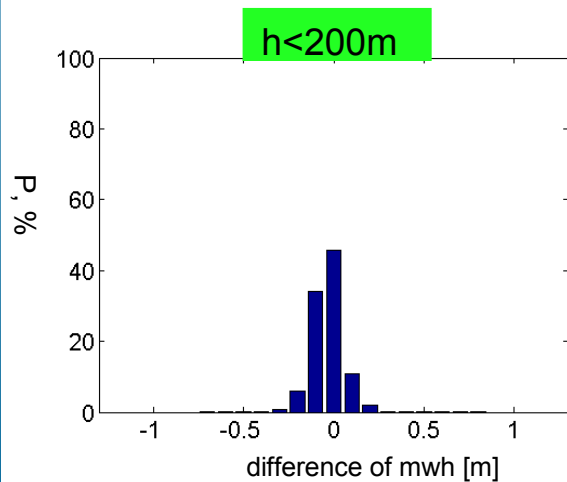

# Influence of mesh resolution on mwh

$$\eta_{\max}^{\text{fine\_mesh}} - \eta_{\max}^{\text{medium\_mesh}}$$

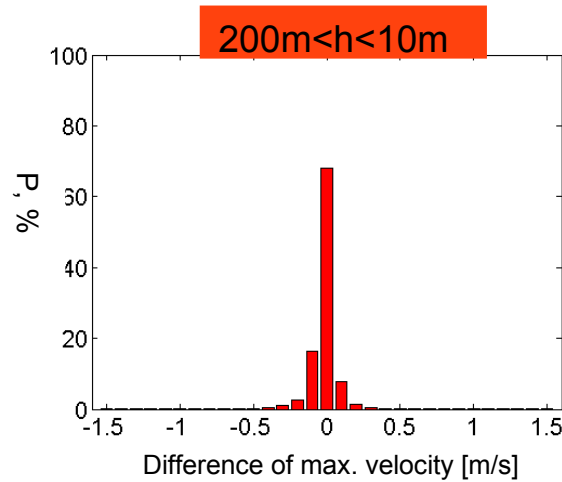

$$\eta_{\max}^{\text{medium\_mesh}} - \eta_{\max}^{\text{coarse\_mesh}}$$

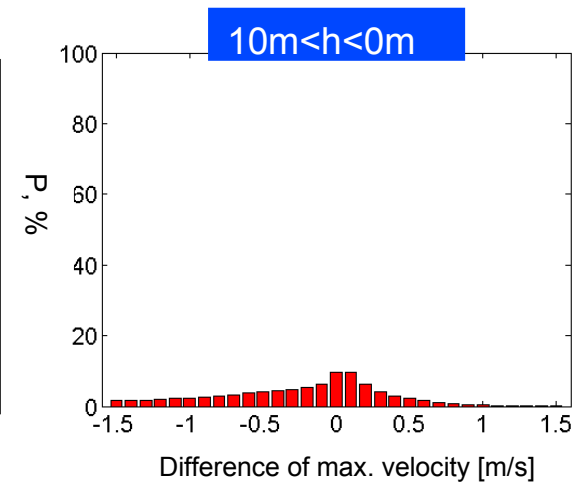

# Influence of mesh resolution on max. velocity

$$|V_{\max}|_{\text{fine\_mesh}} - |V_{\max}|_{\text{medium\_mesh}}$$

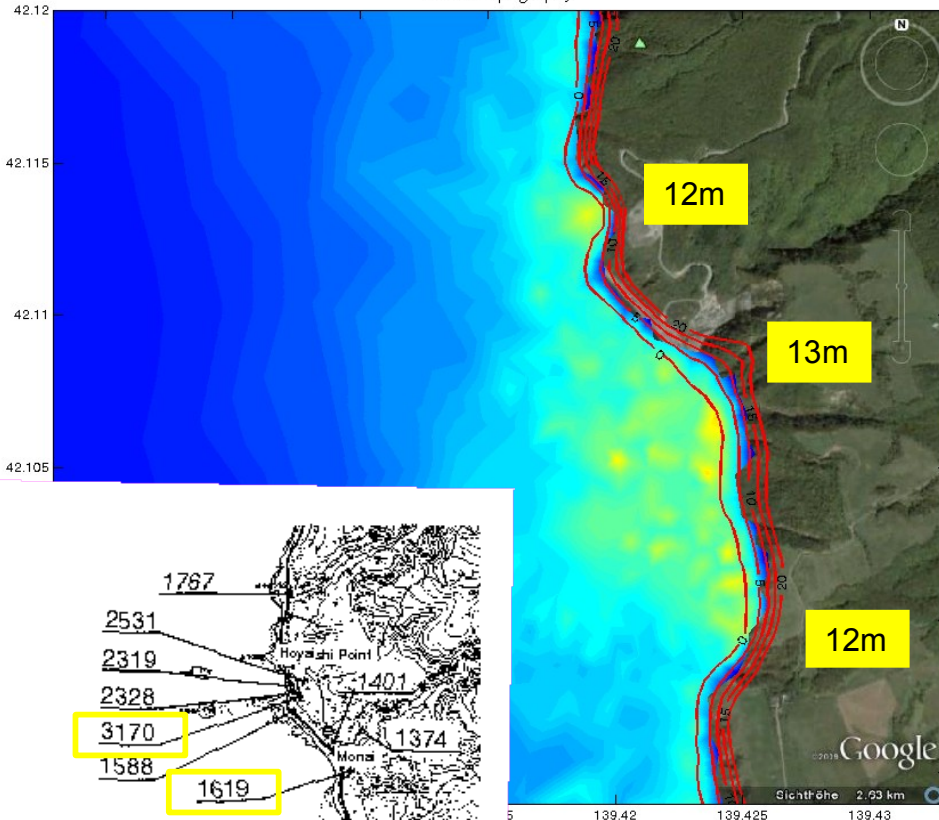

$$|V_{\max}|_{\text{medium\_mesh}} - |V_{\max}|_{\text{coarse\_mesh}}$$

# Inundation of the Monai area – with and without friction

friction parameter:  $n=0.02$

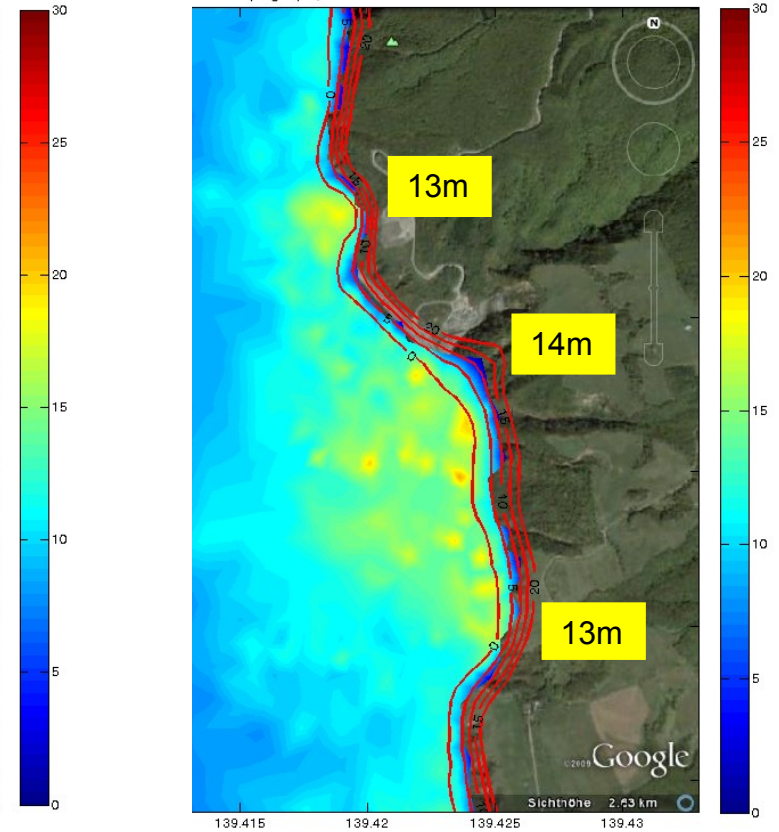

NOAA topography

Runup distribution in the Monai area (in cm)

without friction

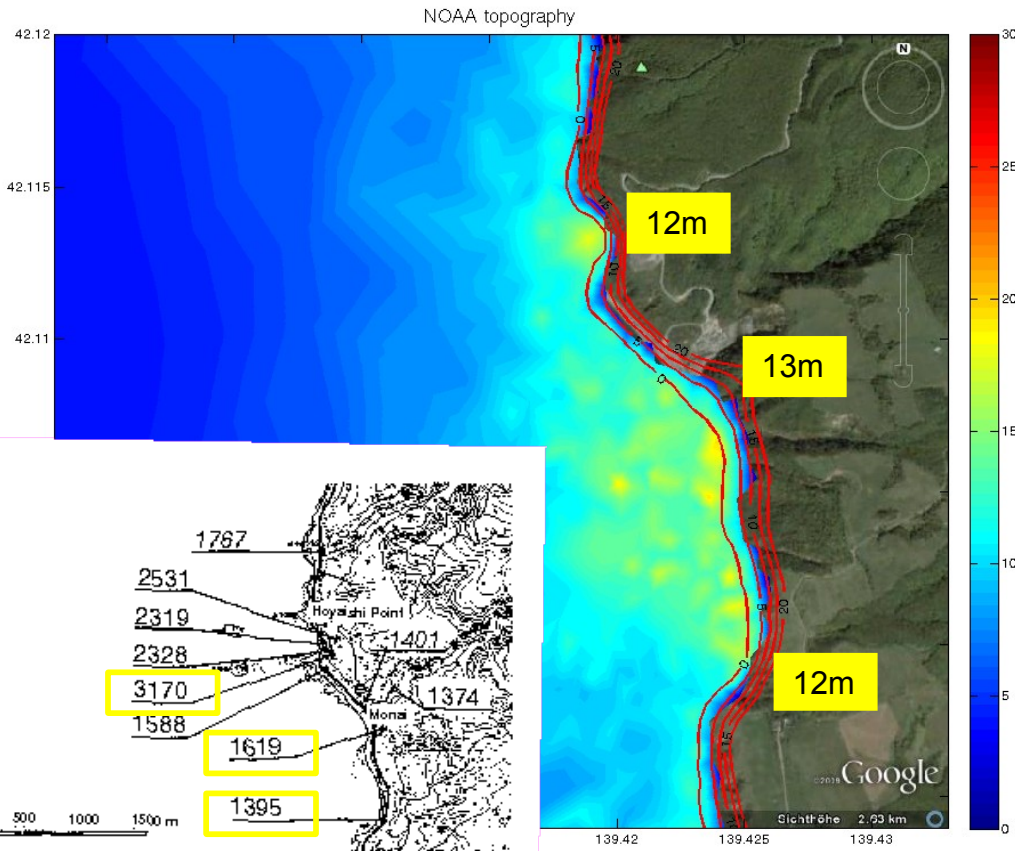

NOAA topography

Max. wave height  
— isolines of topography (0m,5m,10m,15m,20m )

# Inundation of the Monai area – depending on mesh resolution

50 m res. at the coast

Runup distribution in the Monai area (in cm)

10 m res. at the coast

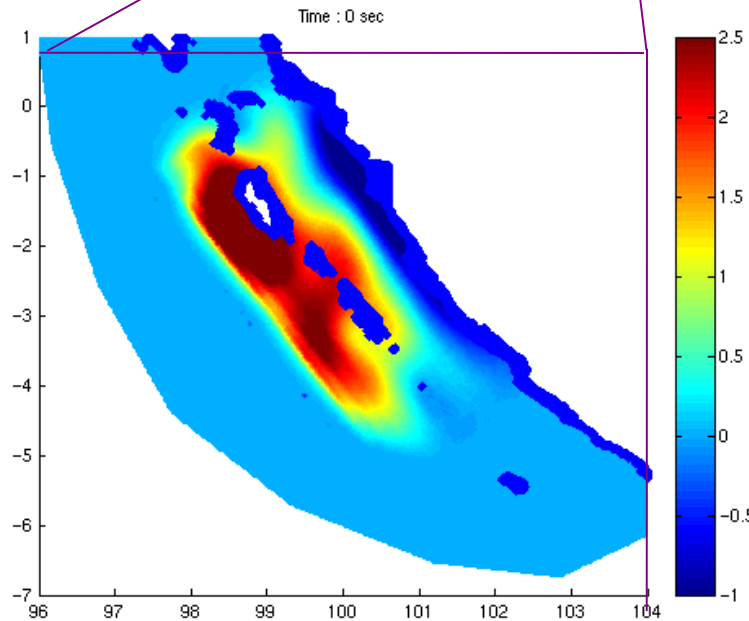

Max. wave height

— isolines of topography  
(0m,5m,10m,15m,20m)

# Worst case tsunami scenario for Padang, Sumatra

**M<sub>w</sub> 8.98**

Max. Uplift = 3.73 m  
Max. Depression = -1.60 m

Variable resolution of the mesh:  
~57 m in Padang region  
~7 km in deep sea

# Worst case tsunami scenario for Padang

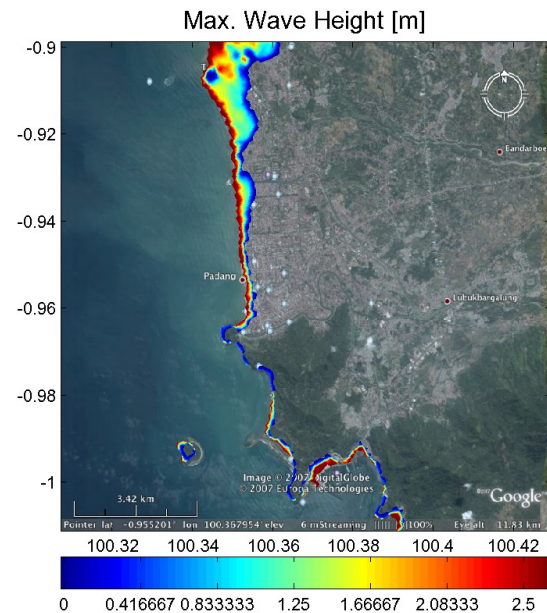

## Topography and inundation results

SRTM  
(90 m res.)

HRSC  
(50 m res.)

# Conclusion

- Advection is important in shallow water
- Grid resolution has effect on mwh and velocity in coastal regions
- To simulate runup successfully, a fine mesh resolution is needed
- Good topography data is crucial for reliable inundation results
